### Exceptions

Exception  
handling  
Specifications  
and exceptions  
Using exceptions  
in your programs

An **exception** is an event that disrupts the normal flow of a program's code

- Exceptions are present and used in many programming languages
- They are raised by code to signal an exceptional situation
- Your code will both raise (create) exception as well as "treat" them

**NB!**

The presence of an exception does not automatically mean that there's an error in the code

# Exceptions

Arthur Molnar

### Exceptions

Exception  
handling  
Specifications  
and exceptions  
Using exceptions  
in your programs

Most programming languages that support exceptions<sup>1</sup> use a common terminology and syntax

- Raising or throwing exceptions
- Catching or treating an exception
- Exception propagation
- **try** / **raise** (throw) / **except** (catch) keywords

### Exceptions

#### Exception handling

Specifications  
and exceptions  
Using exceptions  
in your programs

**Exception handling** is the process of handling error conditions in a program systematically by taking the necessary action.

```
try:
    Your code goes here
    .....
except Exception_1:
    If there is Exception_1, execute this block.
except Exception_2:
    If there is Exception_2, execute this block.
    .....
else:
    If there is no exception, execute this block.
```

# Exception handling

## Lecture 07

Lect. PhD.  
Arthur Molnar

### Exceptions

#### Exception handling

#### Specifications and exceptions

#### Using exceptions in your programs

A few points from the Python syntax above<sup>2</sup>:

- If you want to catch exceptions, the code has to be in a **try - except** block
- Exceptions are caught using their type
- One try block can catch **one**, **several** or **all** exception types
- Creating exceptions in your code is done using the **raise** keyword
- You can provide additional arguments (e.g. an error message) to any Exception you raise

---

Arthur Molnar

### Exceptions

#### Exception handling

#### Specifications and exceptions

#### Using exceptions in your programs

An exceptions can be **handled** by:

- The function where the exception was raised
- Any function that called the raising function
- The Python runtime - **this will crash your program.**

## Discussion

If the phrase "*unhandled exception has occurred in your application...*" sounds familiar, now you understand what happened!

# Exceptions

Arthur Molnar

### Exceptions

#### Exception handling

Specifications  
and exceptions  
Using exceptions  
in your programs

## When to use exceptions?

- Signal an exceptional situation - the function is unable to perform the promised situation (e.g. function preconditions are violated, or the function encountered a situation in which it cannot progress - a required file was not found, is not accessible, etc.)
- Enforce function preconditions
- Generally speaking, you should **not use** exceptions to control program flow!

# Function specification

Arthur Molnar

### Exceptions

Exception  
handling

Specifications  
and exceptions

Using exceptions  
in your programs

Is a way for abstracting **functions** that will only work if we provide:

- Meaningful name for the function
- Short description of the function (the problem solved by the function)
- Type and meaning of each input parameter
- Conditions imposed over the input parameters (**preconditions**)
- Type and meaning of each output parameter
- Relation between the input and output parameters (**post condition**)
- **Exceptions** that the function may raise

# Function specification

## Lecture 07

Arthur Molnar

### Exceptions

Exception  
handling

Specifications  
and exceptions

Using exceptions  
in your programs

- **Precondition** - a condition that must be true just prior to the execution of some section of code.
- **Post condition** - a condition that must be true just after the execution of some section of code.

```
def gcd(a,b):
```

```
    '''
```

```
    Return the greatest common divisor of  
    a and b
```

```
    Input: a,b - integers
```

```
    Output: An integer that is the greatest  
    common divisor of a and b
```

```
    Raise ValueError if a<=0 or b<=0
```

```
    '''
```

# Test case for exceptions

Using exceptions  
in your programs

How do we integrate exceptions into our test cases?

- Sometimes, a function works correctly if it raises an exception, and this must be tested

## Demo

Test cases for functions throwing exceptions,  
**08-TestDrivenDevelopment-2.py**, test function  
**testFindGoldbachPrimes()**

# Exceptions and layered architecture

## Lecture 07

handling

Specifications  
and exceptions

Using exceptions  
in your programs

How do we integrate exceptions into layered architecture programs?

**NB!**

- UI module(s) should not do a lot of processing
- Non-UI modules should not have any UI input/output

Our solution:

- We create exception with an argument or error message
- We catch them in the UI and display the corresponding message
